Atherosclerosis is a complex chronic disease characterized by the accumulation of lipids within arterial walls that eventually go on to form plaques, which can cause narrowing, hardening, and/or complete blockage of arteries. One well known risk factor in humans is hypercholesterolemia (i.e. elevated total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C)) (1), and other important contributors to this disease include inflammation, oxidative stress, and insulin resistance (2,3). Foods high in dietary saturated fat (SF) and cholesterol (i.e. “Western-type diets”) have been linked to elevations in circulating cholesterol levels (in particular, LDL-C) (4), prompting the recommendation that humans limit the intake of these dietary constituents (5). Like humans, Western-type diets can induce elevated LDL-C and atherosclerosis in certain rodent models (i.e. mice, hamsters, guinea pigs). Therefore, the use of such diets for promoting atherosclerosis in these models has been a valuable tool for both gaining more understanding of this disease and testing therapies that can potentially reverse it.

In the past, Western-type diets have been made by adding high levels of fat and cholesterol to grain-based chow diets. The addition of ingredients to chows can dilute other nutrients (i.e. vitamins, minerals, protein, etc) and non-nutrients (i.e. phytoestrogens), so their use in atherosclerosis research has been criticized (6). In order to avoid this issue, purified ingredient diet formulas which are open to avoid this issue, purified ingredient diet formulas which are open

FIGURE 1. Oil red O–stained atherosclerotic lesions in aortas of LDLR2/2 mice fed diets varying in fat, cholesterol, and cholate content. Mice were killed after being fed defined diets for 12 weeks. Aortas were prepared and stained with oil red O as described in Methods. One representative aorta from a total of 6 in each of the 4 dietary groups is shown. Graphic representation – for details see reference (38).

is found in high density lipoproteins (HDL-C), which contributes to their reduced susceptibility to atherosclerosis. Western-type diets containing moderately high levels of SF (~35 kcal% fat), such as (cocoa butter, palm oil, or dairy butter), cholesterol (~0.5 to 1% w/w), and cholic acid (~0.1% to 0.5% w/w), are capable of inducing elevations in TC and LDL-C and mild atherosclerosis (i.e. cholesterol laden foam cells, fatty deposits or streaks) in some mouse strains after 12 weeks (14-16). The presence of cholic acid aids cholesterol and fat absorption, and also suppresses conversion of cholesterol to bile acids (17). This latter effect reduces removal of cholesterol and increases cholesterol levels (in particular, non-HDL-C) which allows atherosclerosis induction to occur in susceptible mouse strains. While it is possible to induce atherosclerosis in some mice, it is important to realize that the presence of cholic acid can influence transcription factors controlling genes involved with regulating lipoprotein metabolism and inflammation, both of which are important in the development of atherosclerosis (16,17), and can also promote gallstones in certain mouse strains (18,19).

Like mice, commonly used outbred rat strains (i.e. Sprague-Dawley, Wistar) typically have high levels of HDL-C and low levels of LDL-C. Western-type diets (~45 kcal% fat as hydrogenated coconut oil) or even low-fat diets (~12 kcal% fat as corn oil) with high levels of cholesterol (~1% w/w) and cholic acid (~0.5% w/w) are capable of promoting elevations in TC and LDL-C in Sprague-Dawley or Wistar rats (20-22) likely by reducing bile acid production (23). Despite such elevations, this alone will not promote atherosclerosis in rats unless a thyroid hormone inhibitor (2-thiouracil, ~0.5% w/w) is added to the diet (24). However, rats that have been selectively bred with spontaneous gene mutations such as the JCR:LA Cohpurulent rat can develop hypercholesterolemia and are sensitive to dietary cholesterol without the need for cholic acid or thyroid hormone inhibitors (25).

Wild Type Mice and Rats

Wild type mice, such as the C57BL/6 mouse, are relatively resistant to atherosclerosis, but have the capacity to develop mild atherosclerosis under certain conditions. Unlike humans, they typically have a very low proportion of TC as LDL-C, and most cholesterol in circulation
Atherosclerosis

Hamsters

Like mice and rats, hamsters typically have a high percentage of HDL-C. However, Western-type diets high in cholesterol (~0.5% w/w) and SF (15 – 20% butter fat w/w) can elevate plasma TC and LDL-C and promote appreciable atherosclerosis (i.e. fatty streaks, foam cells) without the use of cholic acid in as little as 6 weeks (26). Hamsters don’t require cholic acid because dietary cholesterol (even as high as 1% w/w) has little influence on their bile acid synthesis pathways (27), allowing excess dietary cholesterol to enter the blood circulation rather than being converted to bile acids and excreted in the feces. Furthermore, these animals possess cholesterol ester transfer protein (CETP) like humans (but not mice and rats), which allows the transfer of cholesterol from HDL to LDL particles in plasma. Certain SFs (relative to unsaturated fats) and cholesterol both have some ability to promote this pathway (27), and this, in combination with their ability to reduce LDL-C uptake by the liver (28) allows for significant elevations in LDL-C and eventual atherosclerosis induction. These animals are highly sensitive to particular saturated fatty acids as a Western-type diet high in potent cholesterol-raising SF from hydrogenated coconut oil (lauric and myristic acids) can cause even more aortic cholesterol accumulation than a high cholesterol (0.15%) diet with a more cholesterol neutral fat such as cocoa butter (palmitic, oleic and stearic acids) (29).

Additionally, dietary protein type can also influence LDL-C levels and atherosclerosis as hamsters fed casein and lactalbumin had levels higher than those fed an equal amount of soy protein, and like humans, males may be more susceptible than females (31).

Guinea Pigs

Unlike other rodents, guinea pigs have a cholesterol profile similar to most humans (higher proportion TC as LDL-C) when maintained on a low fat/low cholesterol diet. Like hamsters, they possess CETP (30) and do not require cholic acid for atherosclerosis induction and cholesterol elevation (31, 32). They are highly sensitive to changes in dietary fatty acid composition as Western-type diets high in SF (i.e. palm kernel oil, ~80% SF) without dietary cholesterol can elevate TC and LDL-C levels relative to those containing less SF (i.e. palm oil, beef tallow, ~50% SF) (31). The type of protein (i.e. high casein vs soy protein ratio) (32), or carbohydrate (i.e. high sucrose) (33) can exacerbate the condition. The use of a Western-type diet with added cholesterol (at least up to 0.3%, w/w) can cause further elevations in TC and LDL-C and induce atherosclerotic lesions (i.e. fatty streaks) after 12 weeks (34-36). The carbohydrate to fat ratio also has been found to have some importance in promoting atherosclerosis as high cholesterol diets (0.25%, w/w) that are high in carbohydrate (42 kcal%) and moderately high in fat (35 kcal%) are more capable of promoting atherosclerosis than those low in carbohydrate (11 kcal%) and high in fat (55 kcal%) (37).

Genetically Modified Mouse Models

More recently, mouse models have been developed with genetic mutations causing them to be more atherosclerosis prone, promoting atherosclerotic plaques similar to those found in humans. Some well known examples of genetically modified mice used in atherosclerosis research include the LDL receptor (LDLr) null and apolipoprotein E (apoE) null mouse which have mutations that hinder removal of circulating cholesterol by the liver. The use of Western-type diets with added cholesterol (0.15% - 1.25% w/w) which are cholic acid free can induce significant atherosclerotic lesions after 12 weeks in LDLr null mice (38-40). Lesion development is very dramatic in apoE null mice fed a Western-type diet and beginning stages of atherosclerosis (i.e. fatty streak lesions) can be found at 6 weeks (41). With these mouse models, the main influence on atherosclerosis has been found to be dietary cholesterol rather than the level of fat (42-44), but certain threshold levels of dietary cholesterol may exist at least within the context of a low-fat purified diet (45). While very high fat diets (i.e. 60 kcal% fat) are capable of inducing some atherosclerosis, the addition of cholesterol to such diets promotes more atherosclerosis in LDLr null mice (46). Furthermore, the fatty acid profile and even the carbohydrate form (i.e. fructose, sucrose) can be manipulated to modify the atherosclerosis phenotype to the researcher’s advantage (39, 42, 47).

Atherosclerosis

Contact our Resource Center for valuable insight from more than 25 years of product experience in the field of atherosclerosis. Let us formulate the diets to meet your specific needs.

Custom OpenSource Diets
Research Diets, Inc. has pioneered the formulation and production of diets leading to atherosclerosis/ hypercholesterolemia in rodents. Our scientists specialize in providing custom purified OpenSource diets. By carefully designing the diet formula to fit your protocol, you have complete control over small or large changes in diet composition. Plus you are able to report what your animals were fed, repeat the formula and revise diet composition as necessary.

Incorporated Test Compounds
Research Diets, Inc. will incorporate your test compound into pelleted diets for simple, safe dosing. Feeding test compounds eliminates dosing related stress to the animal, eliminates vehicle effects, and saves time and labor. Consult with one of our scientists on the formula, determine the dosage required and the diet will be produced and shipped in 5 to 7 business days.

Value Added Resource
The value of our products is in the scientific support we provide. Our Resource Center is staffed with Masters and Ph.D. level scientists with access to over 14,000 original formulas and a database of more than 3,800 journal articles. We welcome the opportunity to talk science with Ph.D. level scientists with access to over 14,000 original articles. We welcome the opportunity to talk science with Ph.D. level scientists with access to over 14,000 original articles.
